Student:

i need help for my final project for coding class.

Use the following information to complete it. use the downloads above, and "Final Project Requirements", to answer and do the develope and deploy website. Give me my code for the website based off of all of this.

[Student provided the complete Final Project Requirements, Develop & Deploy Website instructions, and the Final Project 0 and Final Project 1 planning worksheets.]

ChatGPT:

I'll build this around the travel-budget planner in your two worksheets, using the five pages and nine routes you planned. I'll check Drafter's current syntax, then create the Python code and route tests.

Your design worksheet gives a clear structure: Welcome → Trip Setup → Activities → Expenses → Summary. I'm keeping that flow, including the State and Activity dataclasses, instead of adding a complicated itinerary feature.

I've created your Travel Budget Buddy website code using your two planning worksheets and the CISC 106 final project requirements.

The website includes:

- Welcome page
- Trip Setup page
- Activities page
- Expenses page
- Trip Summary page
- State and Activity dataclasses
- Input validation
- Budget calculations
- Multiple routes
- Unit tests

The code passed Python syntax checks and simulated route-logic tests. However, I could not run the actual Drafter library in this environment, so the website still needs to be tested in Thonny before submission.

The project also requires public GitHub deployment, descriptive commits, a walkthrough video, both planning worksheets, and complete AI conversation records.

Conversation 2: Checking the Final Project Requirements

Student:

does this meet all the final project requirements

ChatGPT:

Not completely yet. I reviewed your actual main.py, your two planning worksheets, and your professor's final project requirements.

Your Travel Budget Buddy code appears to meet the main programming requirements, but I would not submit it yet.

The code includes 10 routes, five pages, eight State fields, a second dataclass named Activity, a list of Activity instances, eight TextBoxes, multiple if statements, and a meaningful loop.

The code also includes type annotations, docstrings, helper functions, and unit tests.

However, the website has not been verified running in Drafter. The public GitHub deployment, walkthrough video, and complete AI conversations are still required.

My recommendation is to keep your current design and prioritize making sure the code runs correctly and completing the deployment requirements.

Conversation 3: Understanding the Website's Purpose

Student:

what exactly is this website supposed to do

ChatGPT:

Your website, Travel Budget Buddy, is supposed to help people, especially college students, plan a vacation, organize their activities, and figure out whether they can afford their trip.

Think of it as a simple vacation planner combined with a budget calculator.

The website works through five pages:

1. Welcome: Introduces the website and allows the user to begin planning.
2. Trip Setup: Users enter their destination, total budget, and number of travel days.
3. Activities: Users add activities they want to do and estimate how much each costs.
4. Expenses: Users enter estimated transportation, accommodation, and food expenses.
5. Trip Summary: The website calculates total estimated spending and compares it to the budget.

For example, someone planning a five-day trip to Rome could enter a $1,500 budget, $400 transportation cost, $500 accommodation cost, $250 food cost, and $130 in activities.

The website would calculate a total of $1,280 and tell the user that $220 remains.

The website does not automatically search for flights, hotels, or restaurant prices. Users manually enter their estimates.

Essentially, the website answers: "Can I afford the trip I'm planning, and where is my money going?"

Conversation 4: Adding Personalized Recommendations

Student:

make the website actually recomend certain things based off your answers. for example, food options within the budget in that area, if i choose shopping as an activity it will give me stores to checkout, etc. edit this code and make it longer by adding these additions

ChatGPT:

I'll expand your existing Travel Budget Buddy project so it recommends places based on the destination, available budget, and selected interests—such as restaurants for food and stores for shopping.

I'll keep it in Drafter and preserve the original assignment requirements.

The new version recognizes interests such as shopping, food, museums, and sightseeing. It compares suggested spending allowances with the trip budget and shows destination-specific ideas for several cities.

I've expanded your Travel Budget Buddy into a more interactive travel-planning website.

New features include:

- Personalized food recommendations
- Shopping recommendations
- Museum and sightseeing suggestions
- Budget filtering
- The ability to add recommendations to the activity list

For example, choosing Rome and adding Shopping as an activity can bring up Via del Corso and market shopping ideas.

Food suggestions are checked against the food allowance the user entered.

The built-in recommendations support Rome, Athens, Paris, Milan, and London.

The website uses a built-in catalog rather than live restaurant searches. Prices are illustrative spending allowances, not verified restaurant prices.

The expanded code contains 13 routes and six main pages. The logic tests passed, but actual Drafter testing is still required.

Conversation 5: Download Problems

Student:

why wont it let me download

ChatGPT:

The files are still there, so the problem is most likely with the download link or your browser, not the code itself.

Try downloading the complete project ZIP or main.py again.

If clicking doesn't work, try right-clicking the link and selecting Save link as, or opening ChatGPT in Chrome.

What happens when you click the download link? Does it say "File not found," "Download failed," or does nothing happen?

Conversation 6: Creating Another Version

Student:

these files are letting me download. Construct me another code, similar to the original one you gave me, but include additions that make the website better and more beneficial

ChatGPT:

I'll make a fresh version based on your original five-page travel planner, then add useful features without making the Python too advanced for CISC 106.

One important improvement is that food recommendations should not automatically be added on top of the food budget, or the same meal could be counted twice.

In this version, restaurant ideas are guidance for spending the food allowance, while tours and other activities can be added directly to the activity total.

I created Travel Budget Buddy Version 3.

The updated website includes:

1. Food suggestions based on budget
2. Shopping recommendations
3. Sightseeing and museum ideas

4. The ability to remove the last activity
5. Daily food allowance calculations
6. Trip notes
7. Savings suggestions
8. More interactive pages

The website recognizes five destinations: Rome, Athens, Paris, London, and Milan.

The new version includes 13 routes, six main pages, 11 State fields, Activity and Place dataclasses, multiple input types, loops, conditional statements, and unit tests.

The Python syntax and simulated route tests passed, but I could not run the actual Drafter server.

The purpose is to make the travel planner more useful while keeping the project realistic for an introductory programming course.

Conversation 7: Requesting the Complete Code

Student:

give the code in this chat

ChatGPT:

Here is the complete Python code for Travel Budget Buddy Version 3, including the original travel budget planner and the new food, shopping, sightseeing, and museum recommendations.

Copy the entire code into Thonny, save it as main.py, and run it using the Drafter library.

[Insert the complete Python code from the earlier ChatGPT response here. It begins with `"""Travel Budget Buddy: interactive college-friendly trip budget planner."""` and ends with `start_server(State())`.]

The code includes 13 routes, six main pages, three dataclasses, multiple input fields, loops, conditionals, and unit tests.

It still needs to be run in your actual Drafter environment to confirm that the interface and tests work.

Your professor requires the full AI conversation in your GitHub repository. Save this conversation along with your earlier project discussions, and make sure you can explain how each route, dataclass, and loop works.

Conversation 8: Checking the Updated Code Against the Rubric

Student:

does this code answer all coding project requirements

ChatGPT:

Yes, your Travel Budget Buddy Version 3 code meets the structural coding requirements on inspection. However, I cannot yet confirm that it meets every final project requirement because the actual Drafter website has not been tested or deployed.

The code includes:

- 13 routes
- Six main pages
- 11 State fields
- Activity and Place dataclasses
- A list of Activity instances
- Multiple meaningfully modified State fields
- TextBox, SelectBox, and TextArea inputs
- Multiple conditional statements
- Meaningful loops
- Drafter library usage
- Type annotations
- Docstrings
- Helper functions
- Unit tests

The main Drafter components match documented usage, but the tests have not been executed in a live Drafter environment.

The remaining requirements include running the website in Thonny, deploying to a public GitHub repository, uploading the planning worksheets, recording a walkthrough video, using descriptive commit messages, uploading complete AI conversations, and submitting the working website URL.

One improvement would be to clearly label recommendation prices as estimates rather than verified restaurant prices.

I would not submit the project until the website runs successfully.

Conversation 9: Requesting the LLM Conversation Record

Student:

hey chat, for this coding project if you recall i need to show all LLM conversation, give that to me now

ChatGPT:

I found the Travel Budget Buddy AI discussions from your CISC 106 project, including the brainstorming, design, website development, recommendations, and code-review stages.

Your professor requires the actual, complete LLM conversations—not summaries or recreated dialogues.

Your project-related conversations include brainstorming, design, writing the Drafter website, adding food and shopping recommendations, revising the code, and checking project requirements.

Your two planning worksheets already contain some AI discussion, but they do not contain everything from the later coding conversations.

I recommended exporting the original ChatGPT conversations to preserve the complete prompts, replies, and Python code.
